The Third Law of Thermodynamics. The third law of thermodynamics states that the entropy of a system approaches a constant value as the temperature approaches absolute zero. The entropy of a system at absolute zero is typically zero, and in all cases is determined only by the number of different ground states it has.

The four fundamental laws of thermodynamics express empirical facts and define physical quantities, such as temperature, heat, thermodynamic work, and entropy, that characterize thermodynamic processes and thermodynamic systems in thermodynamic equilibrium. They describe the relationships between these quantities, and form a basis for precluding the possibility of certain phenomena, such as ...

Thus the two intensive properties which we use to determine the pressure at state (3) are $T_3 = 300^\circ\text{C}$, and $v_3 = 0.2$. On scanning the superheat tables we find that the closest values lie somewhere between 1.2 MPa and 1.4 MPa, thus we use linear interpolation techniques to determine the actual pressure P_3 as shown below: Solved Real World Example

Thermodynamics - Wikipedia

Mathematically, we can simply write the zeroth law of thermodynamics as \[If $T_1 = T_2$, and $T_1 = T_3$, then $T_2 = T_3$.] This is the most fundamental way of defining temperature: Two objects must be at the same temperature thermodynamically if the net heat transfer between them is zero when they are put in thermal contact and have reached a thermal equilibrium.
